Special Patterns
In file paths,
means
~ means
Working with Files
To retrieve information from a file, from it. To put information into a file, to it.
CSV (comma separated values) files are one type of plain text file. Plain text files have nosuch as bold text, colors, or fonts.
R and Python expect that when data is stored in CSV (or tab-delimited) files, each observation is a and each variable is a Rows and columns may or may not have names. Data is stored in a rectangle; each row has the same number of columns and each column has the same number of rows.

Concatenating strings means to ______ the strings together.

Data Types

Common data types include:			
BooleanIntegerNumericCharacter			
Boolean variables can be eitherbecomes 0 and		When converted to an in	nteger
Most languages also have special types such as NU from missing value indicators (e.g. NA).	LL or None that indi	cate no value. These special types are di	fferent
Character data is also known as	or	data.	
Strings Tabs, spaces, and new line characters are example	os of	abarnators	
\n is a	es 01	Characters.	
\t is a			
A string without any characters in it (length 0) is	s called an	string.	
Strings are sorted in alphabetical order. Lower ca and lower case letters depends on the program.	use letters are differen	nt from upper case letters. The order of	upper
Strings must be surrounded bybe used, but they must match. Pick one style and			can
"north" is a of "northwest	ern".		

Variables

Variables let us refer to a value with a name. We can use the same name, but change the value.
<- in R, and = in Python, are operators. The name of the variable goes on the side, and the value goes on the Everything on the right hand side is evaluated first before the value is assigned to the variable.
In R and Python, a variable with name age_list is the [same/not the same] is a variable with name Age_list.
If you run this code:
x = 3 $x + 2$ x
the value of x at the end will be
If you run this code:
x = 3 y = x x = x + 1 y = y + 2 y = x + 1
the value of y at the end will be

Lists, Vectors, Arrays

or hold multiple value	es (usually) of the same type.
hold multiple values, possibly of different types.	
Elements are stored in order, and elements can be referenced by 0 or 1 depending on the language. The number of elements in it. An empty list has a	of a list, vector, or array is the
You can an item to the beginning of a list o	
Sometimes, lists can be inside other lists.	
In R and Python, you can take a slice of a list (or R vector) using	ng the list indices:
my_list[a:b]	
Example:	
my_list[3:6]	
In Python, a is the index of the value, EXCLUSIVE (meaning it's not included).	b is the index of the value
In R, the first number is the index of the value INCLUSIVE.	value, and the second number is the index of the
Assigning Values	

To change the value of an element in a list, assign a new value to it:

```
my_list = [7,6,5,4]
my_list[2] = 3
my_list
my_list now contains _____
If instead you assign a new value as:
my_list = [7,6,5,4]
my_list = [1,2,3]
my_list
my_list now contains ______.
```

Conditions

[True or False] When using variables with boolean values in a conditional statement, you should explicitly compare them to True or False to determine their value.

The operator to test for equality is _____.

Is the following [True or False]; (TRUE and FALSE) or (not FALSE and TRUE)

Flow Control

If statements determine what to do based on a condition that evaluates to [a single/multiple] True or False value(s).

4	Α	В	С	D
1	Х			
2				
3		>	Х	
4				Х

Figure 1:

Where will the > in cell B3 of Figure 1 above end up if you execute the following statements? The point of the > indicates the direction that is "forward" facing.

```
rotate left
if space ahead of you is occupied
move one space to your left
rotate right
else
move one space forward
move one space forward
if you are in column B
move one space to your left
else if you are facing up
move one space forward
else
move one space backwards
```

For Loops

```
Loops are used to ______ the same code for _____ values.

The following code will print _____ numbers.

x = [1, 4, 3, 6, 7, 2]

for i in x

   if i < 5

        print i
```

Functions

The values you send to a function are called, while the value in the value is a function are called	variables that are defined in a function
The of non-keyword arguments must match the function definition.	of parameters in the
In Python, arguments cannot come before complicated!	arguments. In R, it's more
You can [$always/never$] use the name of all of the parameters when calling	g a function.
It [is/is not] good practice to specify arguments in a function call in the order egardless of whether you're using named/keyword parameters or not.	er they appear in the function definition,
Parameters without default values in a function definition are [${\bf required/op}$	otional].
It's [$\mathbf{OK}/\mathbf{not}\ \mathbf{OK}$] to have variables in your script with the same name as	function parameters.
The output of a function is called the value.	
Packages/Libraries Packages/libraries/modules need to be before using the	om in every script or session. Some are
built-in, while others need to be first.	an in every script of session. Some are
It's a [good/bad] idea to use packages written by other people.	
Ways to Execute Code	
When working interactively in the $___$, each input line starts wi	
which may look like >, >>>, or \$ (or something else entirely) with a space aft the code. When the code is done executing, any outp	
prompt will appear again at the start of a new line.	
You can also write a: a file with many lines of code in it run from within your Integrated Development Environment (IDE) such as RS line.
